0.1 Analyze A/B Test Results

This project will assure you have mastered the subjects covered in the statistics lessons. The hope is to have this project be as comprehensive of these topics as possible. Good luck!

0.2 Table of Contents

Introduction

A/B tests are very commonly performed by data analysts and data scientists. It is important that you get some practice working with the difficulties of these

For this project, you will be working to understand the results of an A/B test run by an e-commerce website. Your goal is to work through this notebook to help the company understand if they should implement the new page, keep the old page, or perhaps run the experiment longer to make their decision.

As you work through this notebook, follow along in the classroom and answer the corresponding quiz questions associated with each question. The labels for each classroom concept are provided for each question. This will assure you are on the right track as you work through the project, and you can feel more confident in your final submission meeting the criteria. As a final check, assure you meet all the criteria on the RUBRIC.

```
#### Part I - Probability
```

To get started, let's import our libraries.

```
[72]: import pandas as pd
import numpy as np
import random
import matplotlib.pyplot as plt
%matplotlib inline
#We are setting the seed to assure you get the same answers on quizzes as we
→set up
random.seed(42)
```

- 1. Now, read in the ab_data.csv data. Store it in df. Use your dataframe to answer the questions in Quiz 1 of the classroom.
 - a. Read in the dataset and take a look at the top few rows here:

```
[73]: df = pd.read_csv('ab_data.csv')
df.head(4)
```

```
[73]:
         user_id
                                   timestamp
                                                  group landing_page
                                                                       converted
          851104 2017-01-21 22:11:48.556739
                                                             old_page
                                                                               0
                                                 control
      1
          804228 2017-01-12 08:01:45.159739
                                                 control
                                                             old_page
                                                                               0
      2
          661590 2017-01-11 16:55:06.154213 treatment
                                                                               0
                                                             new_page
      3
          853541 2017-01-08 18:28:03.143765 treatment
                                                             new_page
                                                                               0
```

b. Use the below cell to find the number of rows in the dataset.

```
[74]: df.shape[0]
```

[74]: 294478

c. The number of unique users in the dataset.

```
[75]: df['user_id'].nunique()
```

[75]: 290584

d. The proportion of users converted.

```
[76]: df_user_unique = df
    df_user_unique.drop_duplicates(subset='user_id', keep='first')
    df_user_unique.converted.mean()
```

[76]: 0.11965919355605512

e. The number of times the new_page and treatment don't line up.

```
[77]: df.query('group == "treatment" and landing_page != "new_page" or group !=_\( \to \)"treatment" and landing_page == "new_page"').shape[0]
```

[77]: 3893

f. Do any of the rows have missing values?

```
[78]: df.isnull().sum()
```

```
[78]: user_id 0
timestamp 0
group 0
landing_page 0
converted 0
```

dtype: int64

- 2. For the rows where **treatment** is not aligned with **new_page** or **control** is not aligned with **old_page**, we cannot be sure if this row truly received the new or old page. Use **Quiz 2** in the classroom to provide how we should handle these rows.
 - a. Now use the answer to the quiz to create a new dataset that meets the specifications from the quiz. Store your new dataframe in df2.

```
[79]: df2 = df.query('group == "treatment" and landing_page == "new_page" or group ==_\( \to \)"control" and landing_page == "old_page"').copy()
```

```
[80]: # Double Check all of the correct rows were removed - this should be 0

df2[((df2['group'] == 'treatment') == (df2['landing_page'] == 'new_page')) == □

→False].shape[0]
```

- [80]: 0
 - 3. Use df2 and the cells below to answer questions for Quiz3 in the classroom.
 - a. How many unique **user_id**s are in **df2**?

```
[81]: df2['user_id'].nunique()
```

- [81]: 290584
 - b. There is one **user_id** repeated in **df2**. What is it?

```
[82]: df2[df2.duplicated(['user_id'])]
```

- [82]: user_id timestamp group landing_page converted 2893 773192 2017-01-14 02:55:59.590927 treatment new_page 0
 - c. What is the row information for the repeat **user_id**?

```
[83]: df2.query('user_id == "773192"')
```

```
[83]:
            user_id
                                        timestamp
                                                        group landing_page
                                                                              converted
      1899
             773192
                      2017-01-09 05:37:58.781806
                                                                                      0
                                                    treatment
                                                                   new_page
      2893
             773192
                      2017-01-14 02:55:59.590927
                                                    treatment
                                                                   new_page
                                                                                      0
```

d. Remove **one** of the rows with a duplicate **user** id, but keep your dataframe as df2.

```
[84]: df2.drop_duplicates(subset=['user_id'], inplace=True)
```

- 4. Use df2 in the below cells to answer the quiz questions related to Quiz 4 in the classroom.
 - a. What is the probability of an individual converting regardless of the page they receive?

```
[85]: df2.converted.mean()
```

- [85]: 0.11959708724499628
 - b. Given that an individual was in the control group, what is the probability they converted?

```
[86]: df2.query('group == "control"').converted.mean()
```

- [86]: 0.1203863045004612
 - c. Given that an individual was in the treatment group, what is the probability they converted?

```
[87]: df2.query('group == "treatment"').converted.mean()
```

- [87]: 0.11880806551510564
 - d. What is the probability that an individual received the new page?

```
[88]: df2.query('group == "treatment"').shape[0] / df2.shape[0]
```

- [88]: 0.5000619442226688
 - e. Consider your results from a. through d. above, and explain below whether you think there is sufficient evidence to say that the new treatment page leads to more conversions.

Given that the number of converts from the treatment group is lower than from the control group, one can easily come to the conclusion that the new landing page is not more effective.

```
\#\#\# Part II - A/B Test
```

Notice that because of the time stamp associated with each event, you could technically run a hypothesis test continuously as each observation was observed.

However, then the hard question is do you stop as soon as one page is considered significantly better than another or does it need to happen consistently for a certain amount of time? How long do you run to render a decision that neither page is better than another?

These questions are the difficult parts associated with A/B tests in general.

1. For now, consider you need to make the decision just based on all the data provided. If you want to assume that the old page is better unless the new page proves to be definitely better at a Type I error rate of 5%, what should your null and alternative hypotheses be? You can state your hypothesis in terms of words or in terms of p_{old} and p_{new} , which are the converted rates for the old and new pages.

$$H_0: p_{old} \geq p_{new}$$

$$H_1: p_{old} < p_{new}$$

$$\alpha = 0.05$$

2. Assume under the null hypothesis, p_{new} and p_{old} both have "true" success rates equal to the **converted** success rate regardless of page - that is p_{new} and p_{old} are equal. Furthermore, assume they are equal to the **converted** rate in **ab data.csv** regardless of the page.

Use a sample size for each page equal to the ones in **ab_data.csv**.

Perform the sampling distribution for the difference in **converted** between the two pages over 10,000 iterations of calculating an estimate from the null.

Use the cells below to provide the necessary parts of this simulation. If this doesn't make complete sense right now, don't worry - you are going to work through the problems below to complete this problem. You can use **Quiz 5** in the classroom to make sure you are on the right track.

a. What is the **convert rate** for p_{new} under the null?

```
[89]: p_old = df2.converted.mean()
p_old
```

- [89]: 0.11959708724499628
 - b. What is the **convert rate** for p_{old} under the null?

```
[90]: p_new = df2.converted.mean()
p_new
```

- [90]: 0.11959708724499628
 - c. What is n_{new} ?

```
[91]: n_new = df2.query('landing_page == "new_page"').shape[0]
n_new
```

- [91]: 145310
 - d. What is n_{old} ?

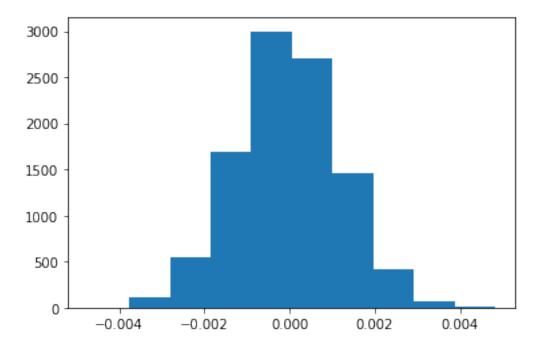

```
[92]: n_old = df2.query('landing_page == "old_page"').shape[0]
n_old
```

- [92]: 145274
 - e. Simulate n_{new} transactions with a convert rate of p_{new} under the null. Store these n_{new} 1's and 0's in **new_page_converted**.

```
[93]: new_page_converted = np.random.choice(a=([0, 1]), size=n_new, p=[1 - p_new, u \rightarrow p_new])
```

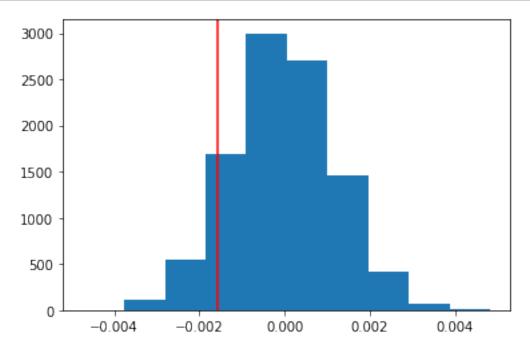

- [94]: new_page_converted.mean()
- [94]: 0.11856031931732158

- f. Simulate n_{old} transactions with a convert rate of p_{old} under the null. Store these n_{old} 1's and 0's in old_page_converted.
- [95]: old_page_converted = np.random.choice(a=([0, 1]), size=n_old, p=[1 p_old, p old])
- [96]: old_page_converted.mean()
- [96]: 0.11988380577391687
 - g. Find p_{new} p_{old} for your simulated values from part (e) and (f).
- [97]: new_page_converted.mean() old_page_converted.mean()
- [97]: -0.001323486456595288
 - h. Simulate $10,000 \ p_{new}$ p_{old} values using this same process similarly to the one you calculated in parts **a. through g.** above. Store all 10,000 values in a numpy array called **p_diffs**.
- [98]: new_converted_simulation = np.random.binomial(n_new, p_new, 10000)/n_new old_converted_simulation = np.random.binomial(n_old, p_old, 10000)/n_old p_diffs = new_converted_simulation old_converted_simulation
 - i. Plot a histogram of the **p_diffs**. Does this plot look like what you expected? Use the matching problem in the classroom to assure you fully understand what was computed here.
- [99]: plt.hist(p_diffs);

j. What proportion of the **p_diffs** are greater than the actual difference observed in **ab_data.csv**?

```
[101]: plt.hist(p_diffs);
plt.axvline(obs_diff, c='red');
```

```
[102]: (p_diffs > obs_diff).mean()
```

[102]: 0.8991

k. In words, explain what you just computed in part **j.** What is this value called in scientific studies? What does this value mean in terms of whether or not there is a difference between the new and old pages?

We computed the probability that we would receive the given obs_diff value under the assumption that the null hypothesis is true. This value is called the p value. The value received, 0.9054, is high, leading to a conclusion that we cannot reject the null hypothesis.

l. We could also use a built-in to achieve similar results. Though using the built-in might be easier to code, the above portions are a walkthrough of the ideas that are critical to correctly thinking about statistical significance. Fill in the below to calculate the number of conversions for each page, as well as the number of individuals who received each page. Let n_old and n_new refer the the number of rows associated with the old page and new pages, respectively.

```
[118]: import statsmodels.api as sm

convert_old = df2.query('group == "control"')['converted'].sum()
convert_new = df2.query('group == "treatment"')['converted'].sum()
n_old = df2.query('landing_page == "old_page"').shape[0]
n_new = df2.query('landing_page == "new_page"').shape[0]
```

```
[122]: n_old, n_new, convert_old, convert_new
```

```
[122]: (145274, 145310, 17489, 17264)
```

m. Now use stats.proportions_ztest to compute your test statistic and p-value. Here is a helpful link on using the built in.

```
[123]: (-1.3109241984234394, 0.9050583127590245)
```

n. What do the z-score and p-value you computed in the previous question mean for the conversion rates of the old and new pages? Do they agree with the findings in parts **j.** and **k.**?

The z-score is how many standard deviations away from the mean a statistic is. A z-score of -1.31 suggests that this statistic is within normal limits given the null hypothesis. The p-value of 0.91 also indicates that the results are common place, if we do not reject the null hypothesis. Therefore, again, we do not reject the null hypothesis.

```
### Part III - A regression approach
```

- 1. In this final part, you will see that the result you acheived in the previous A/B test can also be acheived by performing regression.
 - a. Since each row is either a conversion or no conversion, what type of regression should you be performing in this case?

A logistic regression with dummy variables.

b. The goal is to use **statsmodels** to fit the regression model you specified in part **a.** to see if there is a significant difference in conversion based on which page a customer receives. However, you first need to create a column for the intercept, and create a dummy variable column for which page each user received. Add an **intercept** column, as well as an **ab_page** column, which is 1 when an individual receives the **treatment** and 0 if **control**.

```
[106]: df2['intercept'] = 1
    df2[['bc_page', 'ab_page']] = pd.get_dummies(df['group'])
    df2.drop(columns=(['bc_page']), axis=1, inplace=True)
    df2.head()
```

```
[106]:
          user_id
                                                      group landing_page
                                      timestamp
                                                                           converted

e. What is the p-value associated with **ab_page**? Why does it differ from the value you found in **Part II**? **Hint**: What are the null and alternative hypotheses associated with your regression model, and how do they compare to the null and alternative hypotheses in the **Part II**?

The p-value is 0.1899. This differs from the result in Part II because the coefficient is different and needs to be exponentiated.

f. Now, you are considering other things that might influence whether or not an individual converts. Discuss why it is a good idea to consider other factors to add into your regression model. Are there any disadvantages to adding additional terms into your regression model?

Another option is to consider how time affects conversion. Are dates that occur on weekdays or weekends more or less likely to result in conversion? The disadvantage to adding this criteron into the analysis is that timezones and geographic locations are not present in the data, and without this knowledge any conclusions would be biased due to the missing information.

g. Now along with testing if the conversion rate changes for different pages, also add an effect based on which country a user lives. You will need to read in the **countries.csv** dataset and merge together your datasets on the appropriate rows. Here are the docs for joining tables.

Does it appear that country had an impact on conversion? Don't forget to create dummy variables for these country columns - **Hint: You will need two columns for the three dummy variables.** Provide the statistical output as well as a written response to answer this question.

```

[114]: (1.0416437559600236, 0.9901488436829571)

According to the given coefficients, users from CA were 1.04 times as likely to convert as a US user, while users from the UK were 0.99 times as likely as a US user. The p-values for both countries, however, are high and therefore the null hypothesis is not rejected.

h. Though you have now looked at the individual factors of country and page on conversion, we would now like to look at an interaction between page and country to see if there significant effects on conversion. Create the necessary additional columns, and fit the new model.

Provide the summary results, and your conclusions based on the results.

Optimization terminated successfully.

[116]: (1.020813644503746, 0.9892581106136482)

Users from the US who saw the new page were 1.02 times as likely to convert compared to users from CA, while users from the UK who saw the new page were 0.99 times as likely. The p-values for all figures are high, and therefore the null hypothesis is not rejected.

0.3 Final Conclusion: Do Not Reject the Null Hypothesis

The analysis began with a null hypothesis that the old page produces conversions among users at rate that is equal to or greater than the new page. After several observations on the data, the null hypothesis is not rejected. One example of this can be found in the Logistic Regression, which found that users from the treatment group who saw the new page were only 1.02 times as likely to convert, and the coefficient for this value has a p-value of 0.19, far greater than the alpha level of 0.05 required for statistical significance in this test. With these considerations, the null hypothesis is not rejected and the old page should remain in place.

Conclusions

Congratulations on completing the project!

0.3.1 Gather Submission Materials

Once you are satisfied with the status of your Notebook, you should save it in a format that will make it easy for others to read. You can use the **File** -> **Download** as -> **HTML** (.html) menu to save your notebook as an .html file. If you are working locally and get an error about "No module name", then open a terminal and try installing the missing module using pip install <module_name> (don't include the "<" or ">" or any words following a period in the module name).

You will submit both your original Notebook and an HTML or PDF copy of the Notebook for review. There is no need for you to include any data files with your submission. If you made reference to other websites, books, and other resources to help you in solving tasks in the project, make sure that you document them. It is recommended that you either add a "Resources" section in a Markdown cell at the end of the Notebook report, or you can include a readme.txt file documenting your sources.

0.3.2 Submit the Project

When you're ready, click on the "Submit Project" button to go to the project submission page. You can submit your files as a .zip archive or you can link to a GitHub repository containing your project files. If you go with GitHub, note that your submission will be a snapshot of the linked repository at time of submission. It is recommended that you keep each project in a separate repository to avoid any potential confusion: if a reviewer gets multiple folders representing multiple projects, there might be confusion regarding what project is to be evaluated.

It can take us up to a week to grade the project, but in most cases it is much faster. You will get an email once your submission has been reviewed. If you are having any problems submitting your project or wish to check on the status of your submission, please email us at dataanalyst-project@udacity.com. In the meantime, you should feel free to continue on with your learning journey by beginning the next module in the program.
